

## Quantum Operation

- A general theory of  $\rho \mapsto \mathcal{E}(\rho)$  capturing all physically possible dynamic changes to a state
  - For example, unitary evolution or measurements
  - Physically possible dynamic changes associated with maps on the set of density operators
- **System  $Q$  coupled with environment  $E$** 
  - Model 1:  $QE$  starts in  $\rho \otimes \rho^E$  and undergoes  $U$ 
    - $\rho \mapsto \text{tr}_E(U(\rho \otimes \rho^E)U^\dagger)$
  - Analysis: without loss of generality we assume  $\rho^E = |0_E\rangle\langle 0_E|$  —use purification
    - Let  $\{|i_E\rangle\}$  be basis for  $E$ , define  $E_i \equiv \langle i_E|U|0_E\rangle$  (operator on  $Q$ ), then  $\rho \mapsto \sum E_i \rho E_i^\dagger$ 
      - $U|\psi\rangle|0_E\rangle = \sum (\langle i_E|U|0_E\rangle(|\psi\rangle))|i_E\rangle = \sum (E_i|\psi\rangle)|i_E\rangle$
      - $E_i|\psi\rangle$  is the “ $Q$ -vector” component of  $|i_E\rangle$  in  $U|\psi\rangle|0_E\rangle$
      - Conversely,  $E_i^\dagger|\psi\rangle$  is the  $Q$ -vector component of  $|0_E\rangle$  in  $U|\psi\rangle|i_E\rangle$
    - $\text{tr}_E(U(\rho \otimes |0_E\rangle\langle 0_E|)U^\dagger) = \sum \langle i_E|U(\rho \otimes |0_E\rangle\langle 0_E|)U^\dagger|i_E\rangle = \sum \langle i_E|U|0_E\rangle\rho\langle 0_E|U^\dagger|i_E\rangle = \sum E_i \rho E_i^\dagger$
    - $\sum E_i^\dagger E_i = I \iff \rho \mapsto \text{tr}_E(U(\rho \otimes \rho^E)U^\dagger)$  corresponds to (measuring  $Q$  by  $\{E_i\}$ ) or (measuring  $E$  in computational basis) after undergoing  $U$  with result of measurement lost
    - Partial effects of joint unitary evolution  $\iff$  measurement with outcome lost
  - Example: Consider single-qubit  $Q, E$  with  $U = |0\rangle\langle 0| \otimes I + |1\rangle\langle 1| \otimes X$ , then  $U(\alpha|0\rangle + \beta|1\rangle)|0\rangle = \alpha|00\rangle + \beta|11\rangle$ . Then  $E_1(\alpha|0\rangle + \beta|1\rangle) = \alpha|0\rangle \implies E_0 = |0\rangle\langle 0|$ , similarly  $E_1 = |1\rangle\langle 1|$ .
    - Lost measurement in computational basis corresponds to unitary evolution of  $U|\psi\rangle|0\rangle$
  - $U \equiv \frac{X}{\sqrt{2}} \otimes I + \frac{Y}{\sqrt{2}} \otimes X$ , then  $U(\alpha|0\rangle + \beta|1\rangle)|0\rangle = \left(\frac{X}{\sqrt{2}}|\psi\rangle\right)|0\rangle + \left(\frac{Y}{\sqrt{2}}|\psi\rangle\right)|1\rangle$ 
    - $E_0 = X/\sqrt{2}$ ,  $E_1 = Y/\sqrt{2}$ , corresponds to applying  $X, Y$  randomly with probability  $1/2$
  - Model 2:  $QE$  starts in  $\rho \otimes \sigma$ , undergoes  $U$  and joint projective measurement  $\{P_m\}$ 
    - Remark: General measurement = unitary evolution + projective measurement
    - Let  $\mathcal{E}_m(\rho) \equiv \text{tr}_E(P_m U(\rho \otimes \sigma)U^\dagger P_m)$ ,  $\sigma = \sum q_j |j\rangle\langle j|$ , and  $E_{jk} \equiv \sqrt{q_j} \cdot \langle k_E|P_m U|j\rangle$
    - $\mathcal{E}_m(\rho) = \sum q_j \cdot \text{tr}_E(P_m U(\rho \otimes |j\rangle\langle j|)U^\dagger P_m) = \sum_{jk} E_{jk} \rho E_{jk}^\dagger$

- Given any  $\{\mathcal{E}_m\}$  such that  $\sum \mathcal{E}_m$  is trace-preserving, introduce  $E$  with basis  $|m, k\rangle_E$ , initial state  $|0\rangle_E$ ,  $U : U|\psi\rangle|0\rangle_E = \sum E_{mk}|\psi\rangle|m, k\rangle$ , and  $P_m = \sum_k |m, k\rangle\langle m, k|$ , then
$$\text{tr}_E \left( P_m U (\rho \otimes |0\rangle_E\langle 0|) U^\dagger P_m \right) = \mathcal{E}_m(\rho) / \text{tr}(\mathcal{E}_m(\rho))$$

- $\{\mathcal{E}_m\}$  model-able as  $\mathcal{E}_m(\rho) = \text{tr}_E \left( P_m U (\rho \otimes |0\rangle_E\langle 0|) U^\dagger P_m \right) \iff \mathcal{E}_m(\rho) = \sum E_{mk} \rho E_{mk}^\dagger$

- Trace-preserving:  $\mathcal{E}(\rho) = \text{tr}_E \left( U (\rho \otimes |0\rangle\langle 0|) U^\dagger \right) \iff \mathcal{E}(\rho) = \sum E_k \rho E_k^\dagger, \sum E_k^\dagger E_k = I$

- Axiomatic approach:** we define a dynamic change  $\mathcal{E}$  to system  $Q$  in state  $\rho$  by:

- Nonnegative probability: With initial state  $\rho$ ,  $\mathcal{E}$  occurs with probability  $\text{tr}(\mathcal{E}(\rho)) \in [0,1]$ 
  - Mathematically convenient definition to help cope with measurements
- Convex-linear:  $\mathcal{E} \left( \sum_i p_i \rho_i \right) = \sum_i p_i \mathcal{E}(\rho_i)$

- We wish that  $\rho \sim \{\rho_i, p_i\} \implies \frac{\mathcal{E}(\rho)}{\text{tr}(\mathcal{E}(\rho))} \sim \left\{ \frac{\mathcal{E}(\rho_i)}{\text{tr}(\mathcal{E}(\rho_i))}, p_i \right\}$ , then

$$\mathcal{E}(\rho) = \text{tr}(\mathcal{E}(\rho)) \sum_i p(i | \mathcal{E}) \frac{\mathcal{E}(\rho_i)}{\text{tr}(\mathcal{E}(\rho_i))}. \text{ By } p(i | \mathcal{E}) = \frac{p_i \text{tr}(\mathcal{E}(\rho_i))}{\text{tr}(\mathcal{E}(\rho))} \text{ yields above}$$

- Completely positive: For any (including trivial) system  $R$ ,  $I_R \otimes \mathcal{E}$  maps to positive operators
  - If  $\rho = \text{tr}_Q(\rho^{RQ})$  then after  $\mathcal{E}$  the joint state is still in a valid density matrix
  - Remark: positive *does not* imply completely positive: consider positive map  $\rho \mapsto \rho^\dagger$  applied to the first qubit in  $\beta_{00}$ . Then  $(\rho \mapsto \rho^\dagger \otimes I)$  transposes the  $2 \times 2$  blocks

$$(\rho \mapsto \rho^\dagger \otimes I) \beta_{00} = \frac{(\rho \mapsto \rho^\dagger \otimes I)}{2} \begin{bmatrix} 1 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 1 \end{bmatrix} = \frac{1}{2} \begin{bmatrix} 1 & & & \\ & & 1 & \\ & 1 & & \\ & & & 1 \end{bmatrix} \text{ with}$$

- Theorem:**  $\mathcal{E}$  satisfies axioms above  $\iff \mathcal{E}(\rho) = \sum_i E_i \rho E_i^\dagger$  and  $\sum_i E_i^\dagger \rho E_i \leq I$

- $\sum_i E_i \rho E_i^\dagger$  obviously satisfies axioms 1 & 2, to show complete positivity: let  $A$  be any positive operator on  $RQ$ , and  $|\psi\rangle$  be any state of  $RQ$ , then by  $A$  positive

$$\langle \psi | (I \otimes \mathcal{E}) A | \psi \rangle = \langle \psi | \sum (I \otimes E_i) A (I \otimes E_i^\dagger) | \psi \rangle = \sum \langle \psi | (I \otimes E_i) A (I \otimes E_i^\dagger) | \psi \rangle \geq 0$$

- Conversely, let  $\{|i_R\rangle\}, \{|i_Q\rangle\}$  span  $R, Q$  and define *maximally entangled state*

$$|\alpha\rangle \equiv \sum |i_R\rangle |i_Q\rangle \text{ and } \sigma \equiv (I_R \otimes \mathcal{E})(|\alpha\rangle\langle\alpha|) = \sum_{ij} (|i_R\rangle\langle j_R|) \otimes \mathcal{E}(|i_Q\rangle\langle j_Q|)$$

- For any  $|\psi\rangle = \sum \psi_i |i_Q\rangle$  on  $Q$ , define  $|\tilde{\psi}\rangle \equiv \sum \psi_i^* |i_R\rangle$  on  $R$ . Then
 
$$\langle \tilde{\psi} | \sigma | \tilde{\psi} \rangle = \langle \tilde{\psi} | \sum_{ij} |i_R\rangle \langle j_R| \otimes \mathcal{E}(|i_Q\rangle \langle j_Q|) | \tilde{\psi} \rangle = \sum \psi_i \psi_j^* \mathcal{E}(|i_Q\rangle \langle j_Q|) = \mathcal{E}(|\psi\rangle \langle \psi|)$$
- Let  $\sigma = \sum |s_i\rangle \langle s_i|$  be some decomposition of  $\sigma$ , then  $E_i |\psi\rangle = \langle \tilde{\psi} | s_i \rangle$  satisfies
 
$$\sum E_i |\psi\rangle \langle \psi| E_i^\dagger = \sum \langle \tilde{\psi} | s_i \rangle \langle s_i | \tilde{\psi} \rangle = \langle \tilde{\psi} | \sigma | \tilde{\psi} \rangle$$
- Remark:  $I \otimes \mathcal{E}$ 's action on maximally entangled state of  $QR$  uniquely determines  $\mathcal{E}$
- $\mathcal{E}$  satisfies axioms  $\iff \mathcal{E}(\rho) = \sum E_k \rho E_k^\dagger, \sum E_i^\dagger E_i \leq I \iff \mathcal{E}(\rho) = \text{tr}_E(PU(\rho \otimes \sigma)U^\dagger P)$
- Unitary freedom in operator-sum representation
  - $\{E_k\}, \{F_k\}$  equivalent if  $\sum E_k \rho E_k^\dagger = \sum F_k \rho F_k^\dagger \iff \forall |j\rangle, \sum E_k |j\rangle \langle j| E_k^\dagger = \sum F_k |j\rangle \langle j| F_k^\dagger$ 
    - $\{E_k, F_k\}$  equivalent  $\iff \forall |j\rangle, \{E_k | j\rangle\}, \{F_k | j\rangle\}$  generate the same density matrix
  - Recall  $\Psi \Psi^\dagger = \Phi \Phi^\dagger \iff \Psi = \Phi U$  then  $\forall i, E_i |j\rangle = \sum_i u_{ki} F_k |j\rangle \implies E_i = \sum u_{ki} F_k$
  - $\{E_k\}, \{F_k\}$  equivalent  $\iff \mathbf{E} = U \mathbf{F}$  with  $\mathbf{E}_i = E_i$  for unitary  $U$ 
    - Matrix multiplication with operator as elements
    - Example:  $E_1 = \frac{I}{\sqrt{2}}, E_2 = \frac{Z}{\sqrt{2}}, F_1 = |0\rangle \langle 0|, F_2 = |1\rangle \langle 1|, \begin{bmatrix} E_1 \\ E_2 \end{bmatrix} = \frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix} \begin{bmatrix} F_1 \\ F_2 \end{bmatrix}$
- Any operation over  $E$  with dimension  $d$  may be described by at most  $d^2$  operation elements
  - Assume we have more than  $d^2$  operators  $\{E_i\}$
  - Recall Hilbert-Schmidt inner product  $\langle A, B \rangle = \text{tr}(A^\dagger B)$ 
    - Let  $W_{ij} = \langle E_i, E_j \rangle$ . Easy to see that  $W^\dagger = W$  is Hermitian
  - Lemma:  $W$  has rank at most  $d^2$ 
    - At most  $d^2$  linearly independent operators, so we have row dependence from
 
$$E_j = \sum_{k \neq j} \alpha_k E_k \implies E_j^\dagger E_l = \sum_{k \neq j} \alpha_k^* E_k^\dagger E_l \implies W_{jl} = \sum_{k \neq j} \alpha_k^* W_{kl}$$
  - Diagonalized  $W$  has at most  $d^2$  nonzero diagonal entries, then equivalent operator set  $W \mathbf{E}$  has at most  $d^2$  effective elements
- Trace and partial trace as quantum operation
  - Trace: Let  $E_i = |0\rangle \langle i|$ , then  $\mathcal{E}(\rho) = \sum |0\rangle \langle i| \rho |i\rangle \langle 0| = \text{tr}(\rho) |0\rangle \langle 0|$
  - Partial trace: Given joint system  $QR$  with  $|i_Q\rangle \otimes |j_R\rangle$  basis, then
 
$$E_k \left( \sum \lambda_j |j_Q\rangle \langle j_Q| \right) = \lambda_k |k_Q\rangle \langle k_Q|$$
 satisfies  $\mathcal{E}(\rho) = \sum E_k \rho E_k^\dagger = \text{tr}_R(\rho)$
  - $\sum a_{ij} \cdot E_k |i_Q\rangle \langle j_R| \left( E_k |i_Q\rangle \langle j_R| \right)^\dagger$

- Single-qubit quantum operations

- Trace-preserving operations on single-qubit correspond to affine maps on the Bloch sphere

- Recall:  $\phi : |\psi\rangle\langle\psi| \mapsto \frac{\phi(|\psi\rangle\langle\psi|) \cdot \sigma}{2}$  is linear, and  $\sigma_i |\psi\rangle\langle\psi| \sigma_i^\dagger = \frac{R_i(|\psi\rangle\langle\psi|) \cdot \sigma}{2}$

where  $R_I = I$ ,  $R_{a \in \{x,y,z\}} = R_a(\pi/2)$

## Quantum Error-correction

- Formalism of error-correction
  - An **quantum error-correcting code** is a subspace  $C$  of larger Hilbert space with projector  $P$
  - Noise and recovery are  $\mathcal{E}, \mathcal{R}$  respectively with  $\text{tr} \mathcal{R} = 1$  (recovery must certainly happen)
  - Error-correction condition:  $\forall \rho \in C : (\mathcal{R} \circ \mathcal{E})(\rho) \propto \rho$
- Theorem: Exists ECC for  $\mathcal{E}(\rho) = \sum E_i \rho E_i^\dagger \iff \exists U : P E_i^\dagger E_j P = U_{ij} P$  for Hermitian  $U$ 
  - Consider diagonalization  $U = SDS^\dagger$  and the equivalent operator set for  $\mathcal{E}$ :  $\mathbf{F} = S \mathbf{E}$ 

$$\iff F_k = \sum S_{ki} E_i, \text{ then } P F_i^\dagger F_j P = \sum_{kl} S_{ik}^* S_{jl} \cdot P E_i^\dagger E_j P = \sum_{kl} S_{ik}^* S_{jl} U_{ij} P = d_{kl} P$$
  - $F_k P = U_k \sqrt{P F_k^\dagger F_k P} = \sqrt{d_{kk}} U_k P$ .  $F_k$  rotates  $C$  onto  $\text{Im} U_k P = \text{Im} \left( P_k \equiv U_k P U_k^\dagger = \frac{F_k P U_k^\dagger}{\sqrt{d_{kk}}} \right)$
  - Recall: projector  $P$  must satisfy  $\langle P x, x - P x \rangle = 0 \iff P^\dagger = P^\dagger P$  and  $\text{Im} P = \text{Im} A$
  - Now  $P_l P_k = P_l^\dagger P_k = \frac{U_l P F_l^\dagger F_k P U_k^\dagger}{\sqrt{d_{ll} d_{kk}}} = \frac{U_l d_{lk} U_k^\dagger}{\dots} = 0$  implies  $k \neq l \implies \text{Im}(U_k P) \perp \text{Im}(U_l P)$
  - Syndrome measurement corresponds to  $P_k \equiv U_k P U_k^\dagger$  and correction  $U_k^\dagger$
- Theorem:  $\mathcal{R}$  constructed above for  $\mathcal{E} = \{E_i\}$  also corrects any error  $\mathcal{F} = \{ \sum m_{ji} E_i \}$ 
  - Corollary: we can instead talk about a set of error operators which are correctable

## Quantum Error-Correcting Codes

- (All arithmetic operations taken over  $\mathbb{Z}_2$  in this section)
- A  $[n, k]$  **classical linear code** is a subspace  $C \subset \mathbb{Z}_2^n$  with  $\dim k$ . It encodes  $k$  bits into  $n$  bits
  - Codes are specified as a subspace so may be uniquely determined as kernel or image
  - Remark: linear codes are *closed under addition*
  - **Generating matrix**  $G \in \mathbb{Z}_2^{n \times k}$ ,  $C = \text{Im}(G)$  specifies encoding  $E(x) = Gx \in \mathbb{Z}_2^{n \times 1}$ 
    - Decoding  $D(y') = \text{argmin}_x [d(Gx, y')]$
  - **Parity check matrix**  $H \in \mathbb{Z}_2^{(n-k) \times n}$ ,  $C = \ker(H)$  facilitates
    - Let  $y' = y + e = Gx + e$ , then  $Hy' = He$  characterizes the **error syndrome**.
    - If error syndromes distinct  $H(\{e_i\} \cong \{He_i\})$  then we can identify and correct  $e_i$  from  $Hy'$
  - To ensure  $\dim C = k$  both  $H, G$  must have full rank
  - $C = \text{Im}(G) = \ker(H) \implies HG \in \mathbb{Z}_2^{(n-k) \times 1} = 0$ 
    - $H = [A \in \mathbb{Z}_2^{(n-k) \times k} | I_{n-k}] \iff G = \begin{bmatrix} I_k \\ -A \end{bmatrix}$ . These are called the **standard form**
- Define **Hamming distance**  $d(x, y)$  as the number of indices in which  $x, y$  differ
  - The **Hamming weight**  $\text{wt}(x) \equiv d(x, 0)$ .  $x + y = x - y \implies d(x, y) = \text{wt}(x + y)$
- Define the **distance of code**  $d(C) \equiv \min_{x, y \in C, x \neq y} d(x, y) = \min_{x \in C - \{0\}} \text{wt}(x)$ 
  - Let  $d \equiv d(C)$ , we say that  $C$  is an  $[n, k, d]$  code
- **Theorem: a  $[n, k, d]$  code with  $d \geq 2t + 1$  corrects error on up to  $t$  bits**
  - $y = Gx, y' = y + e$ . Now  $d(y', y) \leq t$  while  $\min_{y_1 \neq y_2} d(y_1, y_2) \geq 2t + 1$ . Decoding is unique
- If any  $d - 1$  columns of  $H$  are linearly independent but some subset of  $d$  columns are linearly dependent  $\iff C = \ker H$  has distance  $d$ 
  - Recall  $x \in C \iff Hx = 0$ . If  $x \neq 0$  and  $Hx = 0$ , condition above implies that  $x$  cannot have  $\leq d - 1$  nonzero entries. The converse is also true
- **Singleton bound: an  $[n, k, d]$  code satisfies  $n - k \geq d - 1$** 
  - An  $[n, k, d]$  code has  $H \in \mathbb{Z}_2^{(n-k) \times n}$  of full rank. Some subset of  $n - k + 1$  columns must be linearly dependent so  $d \leq n - k + 1$
  - Remark:  $H$  full rank  $\implies$  some (generally not all)  $n - k$  columns are independent, so the last result does not imply  $d - 1 = n - k$

- **Hamming codes:** Given  $r \in \mathbb{N}$ , let columns of parity check matrix  $H_r \in \mathbb{Z}_2^{r \times (2^r - 1)}$  be all  $r$ -bit nonzero strings, then  $H_r$  defines a  $[2^r - 1, 2^r - r - 1]$  linear code
- All Hamming codes have distance 3: any two columns are different and some three columns are independent. Hamming codes are  $[2^r - 1, 2^r - r - 1, 3]$  linear codes

• Example:  $H_3 = \begin{bmatrix} 0 & 0 & 0 & 1 & 1 & 1 & 1 \\ 0 & 1 & 1 & 0 & 0 & 1 & 1 \\ 1 & 0 & 1 & 0 & 1 & 0 & 1 \end{bmatrix}$

- **Gilbert-Varshamov bound:** for large  $n$  there exists  $[n, k, d \geq 2t + 1]$  code for some  $k$  s.t.  $k/n \geq 1 - H(2t/n)$  with  $H \equiv -x \log x - (1 - x) \log(1 - x)$ 
  - Prove the Gilbert-Varshamov bound
- Given an  $[n, k]$  code  $C$ , its **dual code**  $C^\perp$  has generator  $H^T$  and parity check matrix  $G^T$ 
  - $x \in C^\perp \iff \forall c^T x = 0 \iff x \in \ker G^T \implies G^T$  parity checks  $C^\perp$
  - A code is **weakly self-dual** if  $C \subseteq C^\perp$  and **strictly self-dual** if  $C = C^\perp$
  - Over  $\mathbb{C}, \mathbb{R}$  fields,  $C^\perp \cap C = \{0\}$  but over  $\mathbb{Z}_2$  field  $C^\perp \cap C$  can be nontrivial
  - Remark: Hamming distance is not a valid inner product in strict sense e.g.  $d(x, x)$  can be 0 for nonzero  $x$ , but it obeys triangle inequality

- Code with generator  $G$  is weakly self-dual  $\iff G^T G = 0$

- Follows from definition:  $G^T G = 0 \iff \text{Im} G \subseteq \ker G^T$

• Lemma:  $\sum_{c \in C} (-1)^{y \cdot c} = \begin{cases} 0 & \text{if } y \notin C^\perp \\ |C| & \text{if } y \in C^\perp \end{cases}$

- $y \in C^\perp \implies \forall c \in C, y \cdot c = 0$
- $y \notin C^\perp \implies \exists c_0 \in C : c_0 \cdot y = 1$  then for every  $c : c \cdot y = 0$  we have  $(c + c_0) \cdot y = 1$ 
  - Bijection between  $\{c \in C : c \cdot y = 0\}$  and  $\{c \in C : c \cdot y = 1\}$

- **Calderbank-Shor-Steane (CSS) codes**

- Given  $[n, k_1]$  code  $C_1$  and  $[n, k_2]$  code  $C_2$  s.t.  $C_2 \subsetneq C_1$  and  $C_1, C_2^\perp$  both correct  $t$  errors

- $\dim C_1 = \dim C_2^\perp = t \implies k_1 = t, n - k_2 = t, \text{ and } k_2 < k_1$

- Remark: we're assuming bit then phase error, but it's without loss of generality up to  $e_1, e_2$

- We can construct an  $[n, k_1 - k_2] = [n, 2t - n]$  quantum code  $\text{CSS}(C_1, C_2)$  as follows:

- Define  $x + C_2 = [x]^{C_2} \equiv \{x' \in C_1 : x' - x \in C_2\} \in C_1/C_2$

- For each unique  $[x]^{C_2}$ , define  $|[x]^{C_2}\rangle \equiv \frac{1}{\sqrt{|C_2|}} \sum_{y \in C_2} |x + y\rangle$

- Define  $\text{CSS}(C_1, C_2) = \text{span}(\{|[x]^{C_2}\rangle\})$ , then  $\dim \text{CSS}(C_1, C_2) = k_1 - k_2$

- $|[x]^{C_2}\rangle$  is well-defined i.e.  $x - x' \in C_2 \implies |[x]^{C_2}\rangle = |[x']^{C_2}\rangle$ 
  - $|x + (y \in C_2)\rangle = |x + (y + x' - x \in C_2)\rangle$
- $|[x]^{C_2}\rangle$  is orthonormal:  $[x]^{C_2} \neq [x']^{C_2} \implies \nexists y_1, y_2 \in C : |x + y_1\rangle = |x' + y_2\rangle$
- Error correction: denote bit and phase errors by  $n$ -bit binary strings  $e_1, e_2$  respectively
  - $|[x]^{C_2}\rangle \mapsto \frac{1}{\sqrt{|C_2|}} \sum_{x \in C_2} (-1)^{(x+y) \cdot e_2} |x + y + e_1\rangle$
  - Apply  $|x\rangle |0\rangle \mapsto |x\rangle |H_1 x\rangle$  obtaining  $\frac{1}{\sqrt{|C_2|}} \sum_{x \in C_2} (-1)^{(x+y) \cdot e_2} |x + y + e_1\rangle |H_1 e_1\rangle$ 
    - Remark:  $x + y \in C_1 \implies H_1(x + y + e_1) = H_1 e_1$
  - Measure second register, obtain  $e_1$ , and correct  $\mapsto \frac{1}{\sqrt{|C_2|}} \sum_{x \in C_2} (-1)^{(x+y) \cdot e_2} |x + y\rangle$
  - $H^{\otimes n}: \frac{1}{\sqrt{|C_2|} 2^n} \sum_{y \in C_2} (-1)^{(x+y) \cdot e_2} \sum_{z \in \mathbb{Z}_2^n} (-1)^{(x+y) \cdot z} |z\rangle = \frac{1}{\sqrt{|C_2|} 2^n} \sum_{y \in C_2} \sum_{z \in \mathbb{Z}_2^n} (-1)^{(x+y) \cdot (z + e_2)} |z\rangle$
  - Substitute  $z' = z + e_2: \frac{1}{\sqrt{|C_2|} 2^n} \sum_{z \in \mathbb{Z}_2^n} (-1)^{x \cdot z'} \left( \sum_{y \in C_2} (-1)^{y \cdot z'} \right) |z' - e_2\rangle$ . Recall lemma
    - Remark:  $+$  and  $-$  are the same in mod-2 arithmetic
  - $\sqrt{\frac{|C_2|}{2^n}} \sum_{z \in \mathbb{C}_2^\perp} (-1)^{x \cdot z'} |z' - e_2\rangle = \frac{1}{\sqrt{|C_2^\perp|}} \sum_{z \in \mathbb{C}_2^\perp} (-1)^{x \cdot z'} |z' - e_2\rangle$
  - Hadamard code takes Hadamard code to itself
    - Apply  $|x\rangle |0\rangle \mapsto |x\rangle |G_2^T x\rangle$ , obtaining  $\frac{1}{\sqrt{|C_2^\perp|}} \sum_{z \in \mathbb{C}_2^\perp} (-1)^{x \cdot z'} |z' - e_2\rangle | - G_2^T e_2\rangle$
  - Measure second register and retrieve  $e_2$  from  $-G_2^T e_2$
  - Correct by applying  $X$  to obtain  $\frac{1}{\sqrt{|C_2^\perp|}} \sum_{z \in \mathbb{C}_2^\perp} (-1)^{x \cdot z'} |z'\rangle$
  - Note how this equals  $H^{\otimes n} \left( \frac{1}{\sqrt{|C_2|}} \sum_{y \in C_2} (-1)^{(x+y) \cdot e_2} |x + y\rangle \right)$  for  $e_2 = \mathbf{0}$

- Apply  $H^{\otimes n}$  to obtain  $\frac{1}{\sqrt{|C_2|}} \sum_{y \in C_2} |x + y\rangle = |[x]^{C_2}\rangle$  as encoded state
- **Shifted CSS** codes: define  $\text{CSS}_{u,v}(C_1, C_2)$  with  $|[x]^{C_2}\rangle \equiv \frac{1}{\sqrt{|C_2|}} \sum_{y \in C_2} (-1)^{u \cdot y} |x + y + v\rangle$
- Lemma:  $\forall u, v$ ,  $\text{CSS}_{u,v}(C_1, C_2)$  has the same coding properties as  $\text{CSS}(C_1, C_2)$ 
  - Equivalent to encoding bit / phase error  $e_1, e_2$  with  $e_1 + u, e_2 + v$
